ABSTRACT

Number of patients with chronic renal failure is increasing from time to time. Hemodialysis is one alternative therapy kidney is the most preferred by patients. Hemodialysis is a process that is carried out by means of a tube to drain blood into the artificial kidney. This study aims to determine the relationship between the level of knowledge and anxiety in patients undergoing hemodialysis readiness is the first time in the RS Bengkulu. This research is the use of cross-sectional design with a sample of patients undergoing hemodialysis in the hospital the first time in Bengkulu province, amounting to 46 respondents, taken with consecutive sampling technique. Data analysis using chi-square and independent t-test at 5%. The results showed no correlation between knowledge and anxiety hemodialysis patients undergoing hemodialysis with readiness the first time. Nurses need to improve the knowledge and health education and counseling for increase the psychological readiness when first responders undergoing hemodialysis.
