Abstrak

Widiastuti A, Sobir, Suhartanto MR. 2010. Diversity analysis of mangosteen (*Garcinia mangostana* L.) irradiated by gamma ray based on morphological and anatomical characteristics. *Nusantara Bioscience* 2: 23-33. The aim of this research was to increase genetic variability of mangosteen (*Garcinia mangostana* L.) irradiated by gamma rays dosage of 0 Gy, 20 Gy, 25 Gy, 30 Gy, 35 Gy and 40 Gy. Plant materials used were seeds collected from Cegal Sub-village, Karacak Village, Leuwiliang Sub-district, Bogor District, West Java. Data was generated from morphological and anatomical characteristics. The result indicated that increasing of gamma ray dosage had inhibited ability of seed to growth, which needed longer time and decreased seed viability. Morphologically, it also decreased plant height, stem diameter, leaf size, and amount of leaf. Anatomically, stomatal density had positive correlation with plant height by correlation was 90% and 74%. Gamma rays irradiation successfully increase morphological variability until 30%. Seed germination after irradiation increased variability and survival rate of mangosteen.
