Abstrak

In adult patients if the jaw discrepancy is too great to compensate for, and camouflage by tooth movement alone, surgery is the only way to obtain a resonable result. Before surgery, the orthodontist must establish not only anteropostrior and transverse position, but also the vertical position of the teeth. Inadequate orthodontic preparation can jeopardize the quality of the surgical result. Occlusion is important but satisfactory facial esthetic must accompany it. A good team work between orthodontist and oral surgeon is the key of succes of the treatment, which will be shown in case reports of 3 patients.
