Abstrak

The demand of implant restorations is increasing due to its superiority in function, safety and comfort. However, aesthetic disharmony commonly occurs, due to metal color, implants profile, position and angulations. To overcome this limitation, it is important to balance the aesthetic with the biomechanical requirements. This requires implant selection (material, shape and angulations), modifying superstructure (retainer, pontic, attachment) to improve improper implants position and angulations and preprosthetic bone augmentation to facilitate implant placement to fulfil aesthetic and biomechanical requirements.
