## Abstrak

Hypertrophic obstructive cardiomyopathy (HOCM) is a genetic disorder associated with significant morbidity and mortality. Patients with this illness are prone to sudden death, angina, syncope, and heart failure. Symptomatic patients with HOCM are usually medically treated; in the few patients with persistent symptoms, surgical myomectomy offers satisfactory control.<sup>1,1</sup> The role of DDD pacing in effort to reduce left ventricular outflow tract (LVOT) gradient is still controversial.<sup>3-4</sup> Recently, non-surgical septal reduction therapy (NSRT) has gained popularity as an alternative to surgery, because the procedure is much simpler, safe and effective for relief of symptoms of LVOT obstruction.<sup>5 7</sup>

This paper will report a case of HOCM successfully treated with NSRT.
