Abstrak

Ganoderma lucidum (hereafter *G. lucidum*) has been known as a food and raw material used in the development of medications because of its high content of polysaccharides, or β -glucans, which support the immune function. In this work, subcritical water was applied to utilize *G. lucidum* for the extraction of polysaccharides at temperatures of 373–463K and a pressure level of 4.0 MPa using a semi-batch system. Furthermore, these extracts were atomized and contacted with hot air to produce microsphere particles. During extraction, thermal softening of *G. lucidum* occurred, allowing the removal of the polysaccharides and protecting other constituents in *G. lucidum* via hydrolysis. Scanning electron microscope (SEM) images showed that the microsphere particles formed were spherical and dimpled or shriveled particles with diameters varying from 1 to 6 μ m. Characteristics of the molecular mass revealed that main massed peaks of water soluble products were distributed at around 688–2636 m/z with a peak-to-peak mass difference of 162 m/z, consistent with the repeating unit of the glucans.
